Problem 1

a)

Since the response variables $y_i \sim \text{Bernoulli}(\pi_i)$, where $\pi_i = \Pr(y_i = 1 \mid \mathbf{x}_i)$. The conditional mean is given by $Ey_i = \pi_i$, which is connected to the covariates via the following relationship:

$$\mathbf{x}_i^T \boldsymbol{\beta} =: \eta_i = \Phi^{-1}(\pi_i),$$

or equivalently: $\pi_i = \Phi(\eta_i)$. This results in the likelihood function

$$\begin{aligned} L(\boldsymbol{\beta}) &= \prod_{i=1}^n \pi_i^{y_i} (1 - \pi_i)^{1-y_i} \\ &= \prod_{i=1}^n \Phi(\eta_i)^{y_i} (1 - \Phi(\eta_i))^{1-y_i}. \end{aligned}$$

Thus, the log-likelihood becomes

$$l(\boldsymbol{\beta}) := \ln(L(\boldsymbol{\beta})) = \sum_{i=1}^n \underbrace{y_i \ln(\Phi(\eta_i)) + (1 - y_i) \ln(1 - \Phi(\eta_i))}_{=l_i(\boldsymbol{\beta})} = \sum_{i=1}^n l_i(\boldsymbol{\beta}).$$

To find the score function, we calculate

$$\begin{aligned} \frac{\partial l_i(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}} &= \frac{y_i}{\Phi(\eta_i)} \frac{\partial \Phi(\eta_i)}{\partial \boldsymbol{\beta}} - \frac{1 - y_i}{1 - \Phi(\eta_i)} \frac{\partial \Phi(\eta_i)}{\partial \boldsymbol{\beta}} \\ &= \frac{y_i}{\Phi(\eta_i)} \phi(\eta_i) \mathbf{x}_i - \frac{1 - y_i}{1 - \Phi(\eta_i)} \phi(\eta_i) \mathbf{x}_i \\ &= \frac{y_i(1 - \Phi(\eta_i)) - (1 - y_i)\Phi(\eta_i)}{\Phi(\eta_i)(1 - \Phi(\eta_i))} \phi(\eta_i) \mathbf{x}_i \\ &= \frac{y_i - \Phi(\eta_i)}{\Phi(\eta_i)(1 - \Phi(\eta_i))} \phi(\eta_i) \mathbf{x}_i. \end{aligned}$$

Consequently, the score function is given by

$$\mathbf{s}(\boldsymbol{\beta}) = \sum_{i=1}^n \frac{y_i - \Phi(\eta_i)}{\Phi(\eta_i)(1 - \Phi(\eta_i))} \phi(\eta_i) \mathbf{x}_i.$$

Next, we find the expected Fisher information, $F(\boldsymbol{\beta})$. We find it by using the result

$$\begin{aligned}
F(\beta) &= \text{Var}(\mathbf{s}(\beta)) = \text{Var}\left(\sum_{i=1}^n \frac{y_i - \Phi(\eta_i)}{\Phi(\eta_i)(1 - \Phi(\eta_i))} \phi(\eta_i) \mathbf{x}_i\right) \\
&= \sum_{i=1}^n \left[\frac{\phi(\eta_i)}{\Phi(\eta_i)(1 - \Phi(\eta_i))} \right]^2 \text{Var}(y_i \mathbf{x}_i) = \sum_{i=1}^n \left[\frac{\phi(\eta_i)}{\Phi(\eta_i)(1 - \Phi(\eta_i))} \right]^2 \mathbf{x}_i \text{Var}(y_i) \mathbf{x}_i^T \\
&= \sum_{i=1}^n \left[\frac{\phi(\eta_i)}{\Phi(\eta_i)(1 - \Phi(\eta_i))} \right]^2 \pi_i(1 - \pi_i) \mathbf{x}_i \mathbf{x}_i^T = \sum_{i=1}^n \frac{\phi(\eta_i)^2}{\Phi(\eta_i)(1 - \Phi(\eta_i))} \mathbf{x}_i \mathbf{x}_i^T,
\end{aligned}$$

Where in the third equality we have used that the y_i 's are independent. The expected Fisher information can also be verified to have this expression by the relationship

$$F(\beta) = \sum_{i=1}^n \frac{h'(\eta_i)^2}{\text{Var}(y_i)} \mathbf{x}_i \mathbf{x}_i^T,$$

where $h'(\eta_i) = \Phi'(\eta_i) = \phi(\eta_i)$ and $\text{Var}(y_i) = \pi_i(1 - \pi_i) = \Phi(\eta_i)(1 - \Phi(\eta_i))$.

b)

The expected Fisher information is given by

$$F(\beta) = \sum_{i=1}^n \frac{\phi(\eta_i)^2}{\Phi(\eta_i)(1 - \Phi(\eta_i))} \mathbf{x}_i \mathbf{x}_i^T = \mathbf{x}^T W \mathbf{x},$$

where $W = \text{diag}\left(\frac{\phi(\eta_i)^2}{\Phi(\eta_i)(1 - \Phi(\eta_i))}\right)$.

The Fisher scoring algorithm states that the next iterate is given by

$$\beta^{(t+1)} = \beta^{(t)} + F(\beta^{(t)})^{-1} \mathbf{s}(\beta^{(t)}).$$

Inserting the expected Fisher information and the score function we get

$$\beta^{(t+1)} = (\mathbf{x}^T W^{(t)} \mathbf{x})^{-1} \mathbf{x}^T W^{(t)} \tilde{\mathbf{y}}^{(t)},$$

where the working response vector $\tilde{\mathbf{y}}^{(t)}$ has element i given by

$$\tilde{y}_i^{(t)} = \mathbf{x}_i^T \beta^{(t)} + \frac{y_i - h(\mathbf{x}_i^T \beta^{(t)})}{h'(\mathbf{x}_i^T \beta^{(t)})} = \eta_i^{(t)} + \frac{y_i - \Phi(\eta_i^{(t)})}{\phi(\eta_i^{(t)})}.$$

litt om deviance her. Litt ullent for meg hva en saturated model er, men dette gir riktig svar i c). We also need the deviance, which is defined as

$$D = 2(l_{\text{saturated}} - l(\hat{\beta})).$$

When we fit a parameter for each data point (which is the case for the saturated model), the result for the Bernoulli distribution is that $\hat{\pi}_i = y_i$. This means that the likelihood function of the saturated model is given by

$$L_{\text{saturated}} = \prod_{i=1}^n \hat{\pi}_i^{y_i} (1 - \hat{\pi}_i)^{1-y_i} = \prod_{i=1}^n y_i^{y_i} (1 + y_i)^{1-y_i} = 1,$$

Where we have used $0^0 = 1$. Consequently, the log-likelihood $l_{\text{saturated}} = \ln(1) = 0$ and the deviance becomes $-2l(\hat{\beta})$. Next follows the Implementation of `myglm` in R:

```

Phi <- function(x) return (pnorm(x))
phi <- function(x) return (dnorm(x))

myglm <- function(formula, data, start = NULL){

  # response variable
  resp <- all.vars(formula)[1]
  y <- as.matrix( data[resp] )

  # model matrix
  X <- model.matrix(formula, data)
  n <- dim(X)[1]
  p <- dim(X)[2]

  # starting beta
  if (is.null(start)){
    beta = rep(0, p)
  }
  else {
    beta = start
  }

  # Fisher scoring algorithm
  max_iter <- 50
  tol <- 1e-10
  iter <- 0
  rel.err <- Inf

  while (rel.err > tol & iter < max_iter){
    # calculate eta, y tilde, W
    eta <- X %*% beta
    y.tilde <- eta + (y - Phi(eta)) / (phi(eta))
    W <- diag( as.vector(phi(eta)^2 / (Phi(eta)*(1-Phi(eta)))), n, n )

    # update beta
    A <- t(X) %*% W %*% X
    b <- t(X) %*% W %*% y.tilde
    beta.new <- solve(A, b)

    iter <- iter + 1
    rel.err <- max(abs(beta.new - beta) / abs(beta.new))
    beta <- beta.new
  }

  # Calculating vcov and deviance.
  F.inv <- solve(A)
  std.Error <- sqrt(diag(F.inv))

```

```

eta = X %*% beta
deviance = -2 * sum(y*log(pnorm(eta)) + (1 - y)*log(1 -pnorm(eta)))

return (list("coefficients" = data.frame(beta, std.Error),
        "deviance" = deviance,
        "vcov" = F.inv))
}

```

c)

Simulation of 1000 Bernoulli draws with a random probability.

```

# probability
x = runif(1000, 0, 1)
# draw n bernoulli with prob x
y <- rbinom(1000, 1, x)
df <- data.frame(y, x)

```
## Df Deviance Resid. Df Resid. Dev Pr(>Chi)
```

```
## NULL 518 719.39
```

```
## age 1 522 517 197.39 < 2.2e-16 ***
```

```
## ---
```

```
## Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

The low p-value suggests that age has an effect on the response variable.

b)

Relating to the juul data set, we define for each observation/individual

$$y_i = \begin{cases} 0, & \text{if menarche has occurred.} \\ 1, & \text{if menarche has not occurred.} \end{cases}$$

and t_i as the age at the time of examination, which corresponds to **age** in the data set. Let $T_i \sim N(\mu, \sigma)$, where T_i is the time until menarche occurs for the i 'th individual. Furthermore, let

$$\begin{aligned} \pi_i &:= P(y_i = 1) = P(T_i \leq t_i) \\ &= P\left(\frac{T_i - \mu}{\sigma} \leq \frac{t_i - \mu}{\sigma}\right) = \Phi\left(\frac{t_i - \mu}{\sigma}\right) \end{aligned}$$

This, in turn, gives

$$\Phi^{-1}(\pi_i) = -\frac{\mu}{\sigma} + \frac{1}{\sigma}t_i = \beta_0 + \beta_1 t_i,$$

where $\beta_0 = -\mu/\sigma$ and $\beta_1 = 1/\sigma$.
